TITLE: Computerized method for improving data resolution

Abstract Text (1):

A data resolution synthesis algorithm takes low resolution source input data (e.g., data degraded from compression or data acquired from low quality imaging devices) to synthesize high resolution output data. In an exemplary embodiment for color printing, the algorithm is performed by characterizing a multi-pixel area, or window, around a pixel that can benefit from resolution enhancement. To interpolate to a high resolution output a set of spatial filters is applied to the data area based on the window characterization. The output of the resolution synthesizer is a set of multiple pixels for each input pixel, representing the source input pixel in a higher resolution enhanced version. The filters are chosen from a stored data base (generic or specifically applicable data base for each type input device) created to fit input/output device requirements.

Brief Summary Text (10):

In color printing, such as with laser or ink-jet dot matrix hard copy apparatus, it may be even simply a user preference to create a print with higher resolution than the source provides in order to provide a sharper, less grainy, smoother textured image to present an overall higher quality and artistic print.

Drawing Description Text (9):

FIG. 6 is a color comparison of images printed without and with the application of the present invention as shown in FIGS. 1-5.

Detailed Description Text (5):

FIG. 1A is a depiction of a system 100 implementing the present invention. A data source 102 has an output of low resolution data 104. Before putting the data 104 into an output device 106 (e.g., a color printer) storage apparatus 108 from which an output version 110 of the input data 104 can be generated, the data 104 is analyzed. When the input data 104 is found to be congruent with the processes of the present invention, further analysis, data enhancement, and resolution synthesis steps 112 can be performed. In the process of analysis, other known manner data enhancements can also be employed to conform the output data 114 to the output device 106 data resolution capabilities, such as a variety of user output options provided in a color printer.

Detailed Description Text (12):

If the user has selected 107 BEST print mode output, but the computer has not requested a resolution upscaling 109, a check is made to determine if the source data was already upscaled 111, e.g., the decompressed JPEG file. For example, decompression may have already upscaled the true source data by a factor of two or more via a simple pixel replication routine (see Background of the Invention section, supra). Alternatively, the source may have stretched the data bidimensionally to fit the output device format [e.g., the Internet provider may know that pixel data needs to be upscaled in order to render a 6.times.9-inch print of the current screen display rather than a 2.times.3-inch print on the 8.5.times.11-inch printer paper]. However, the algorithm used by the application to pre-upscale images is likely a simple and less effective prior art technique. Since

a goal of the present invention is to provide superior upscaling to those techniques while providing an output device resolution matched data set, reversal of such a prior upscaling, or downscaling 113, prior to further analysis and resolution synthesis 121 provides superior final image results.

Detailed Description Text (20):

For a two-times ("2.times.") enhancement--viz., two dimensionally from one input pixel to four output pixels--selection 203 (FIG. 2A) of a window 301 (FIG. 3) of 3.times.3 pixels has been found to present an adequate sample of a local region of an image to be enhanced. Note however that a larger window 305 (e.g., 5.times.5 pixels) could be used in the characterization, filtering, or both routines of the present invention. In experimenting specifically for ink-jet printing implementations, it has been found that use of a larger window both for characterizing a target pixel 303 and for filtering a window may not improve the printed image noticeably within the limitations of human visual perception. Selection of too large a window may lead to the printing of undesirable artifacts if the variations of image characterizing factors is great within the selected window. However, such larger windows may be effective in another specific application (see Background section, supra). Similarly, it is possible to select and use a "double window," one for characterization and another for data filtering. In the alternatives shown in FIG. 3, the outer 5.times.5 pixel window 305 of the image that could be subject to filtering is denoted as observation vector z, while inner 3.times.3 pixel window 301 is used to characterize the nature of the target pixel 303. Thus, the process is adaptable to optimization for different input data sources and output data devices.

Detailed Description Text (27):

If the difference is above the threshold 206-208, indicating enhancement is warranted 206', 207', 208", the process continues on a plane-by-plane basis. Next, a check 211-213 is made of imaging characteristic factor variation for the entire window data subset select 203, again to determine if resolution synthesis is warranted. For example, while a target pixel may vary from the surrounding window as determined in steps 206, 207, 208, if the window 301 itself has little overall color variation--e.g., the image of the white of an eye--applying resolution synthesis could be superfluous to the visual appearance of the final output image and so it can be bypassed in order to speed data processing. In the preferred embodiment, a grey scale luminance value is calculated 211 for the target pixel 303 and each pixel in the window 301.

Detailed Description Text (28):

For the current preferred embodiment useful in computer peripheral color printing, it has been found that suitable results are achieved in a reasonable real time calculation by using grayscale values even though manipulating color data of a form comprising tristimulus color space triplets such as {Red, Green, Blue} or {Cyan, Magenta, Yellow}. Each data triplet value is run through the calculations individually as if it represented a grey scale data coordinate. In other words, each color plane data coordinate of a triplet is treated individually as if it were a single luminance value in grey scale:

Detailed Description Text (29):

It will be recognized by a person skilled in the art that a data base using true color space data can be created and used to created tristimulus color space vectors and data filters but at the cost of adding significantly more memory, logic, and data processing time. As a variety of such techniques are already known in the art, use of true color space data rather than grey scale luminance values is not beyond the scope of the present invention, but no further detail is necessary to an understanding of the present invention. Note that selection of grey scale luminance makes the process suitable for true grey scale image enhancement, e.g., for resolution enhancement of black and white photographs.

Detailed Description Text (30):

The changes in luminance ( $\text{Max } L^* - \text{Min } L^*$ , where  $L^*$  is the standard nomenclature for luminance), over the target pixel window of pixels 301 is calculated and compared 212 to a predetermined threshold. The difference is compared to a first threshold of a range of luminance values. If it is above the first predetermined threshold, the process proceeds. If not above the first threshold, meaning very little variation in the window 301, another simple known in the art enhancement, e.g., pixel replication, or the like, is applied 209. With the process proceeding, the entire window luminance variation of the window is checked 213 against a second predetermined threshold. In other words, a test is made as to whether the average luminance of a window 301 is within a range of color variation--meaning some but not a great deal of variation. Thus, if the difference 213 is above the lower limit, first threshold, of the range of color variation 212 but below the upper limit, second threshold--meaning subtle color variations within the window--a secondary, improved enhancement such as a asymmetric Laplacian filter is applied 215 to the target pixel. That is, within the luminance check range, resolution synthesis may not been found to be warranted, yet known manner enhancement is desired and therefore applied. If in comparison the window luminance variation exceeds the second threshold 213, the process proceeds.

Detailed Description Text (33):

Turning now to FIGS. 2B and 3, assume a window 301, or at least one color plane of the current pixel 303, is selected for resolution synthesis. For the printing implementation of the exemplary embodiment of the present invention, the target pixel window region 301 is characterized 221, 309. The characterization process is depicted in more detail in FIG. 4. Each axis in the 8-dimensional space  $L_0-L_7$  has a designated range of 0 to 255. The target pixel  $L_T$  and eight surrounding pixels  $L_0-L_7$  were converted to gray scale luminance values; now the central target pixel  $L_T$  value is subtracted:

Detailed Description Text (35):

$L_n = \text{luminance value for surround pixel } n,$

Detailed Description Text (36):

$L_T = \text{luminance value for the target pixel, and}$

Detailed Description Text (37):

$V_n = \text{relative } \text{luminance values of } L_T \text{ to } L_n.$

Detailed Description Text (38):

This provides an 8-dimensional vector denoted the cluster vector  $y$  (also sometimes referred to hereinafter as a "window key" or "cluster key"), which is a representation of the given pattern, tone independent, of the window data for the entire pixel window 301. In other words, a real time derived cluster vector  $y$  contains salient image data for the pixel window 301. Cluster vectors  $y$  are assumed to be distributed as a multi-variate Gaussian mixture via this luminance variation value characterization.

Detailed Description Text (46):

In this exemplary embodiment, the provided data base is one hundred and one image resolution data filters (the number of filter classes is constrained only by storage capacity of the particular implementation), each class comprising groups of four data filters that have been generated and classified based upon imagery test data. For the exemplary embodiment, each class is a group of four data filters relating to a luminance grey scale pattern.

Detailed Description Text (66):

Despite the seeming complexity of the new enhanced high resolution image from low resolution image data, it has been found that the data processing time in the efficient resolution synthesis mode is negligible with respect to the average print

time required for a full color print.
